Two-stage Gauss–Legendre Method

Exact one-step Jacobian, symplecticity, and symmetry

Fourth-order collocation method for canonical Hamiltonian systems

1 Hamiltonian convention

Let $z \in \mathbb{R}^{2d}$ and consider the possibly time-dependent canonical Hamiltonian system

$$\dot{z} = f(t,z) = \Omega^{-1}\nabla_z H(t,z), \qquad \Omega = \begin{pmatrix} 0 & I_d \\ -I_d & 0 \end{pmatrix}. \tag{1}$$

For the component-major guiding-centre state

$$z = (x_1, \ldots, x_d, y_1, \ldots, y_d)^T,$$

this convention gives

$$f(t,z) = \begin{pmatrix} -\nabla_y H(t,z) \\ \nabla_x H(t,z) \end{pmatrix}.$$

At any fixed time and state, let $F = D_z f(t,z)$. Since $\nabla_z^2 H$ is symmetric,

$$F^T\Omega + \Omega F = 0. \tag{2}$$

This identity is the infinitesimal Hamiltonian condition used below. The proof remains valid for a time-dependent Hamiltonian because the stage times do not depend on the initial state z_n.

2 Gauss–Legendre stages

Set

$$r = \frac{\sqrt{3}}{6}, \qquad c_1 = \frac{1}{2} - r, \qquad c_2 = \frac{1}{2} + r.$$

The Butcher coefficients of the two-stage Gauss–Legendre method are

$$A = \begin{pmatrix} \frac{1}{4} & \frac{1}{4} - r \\ \frac{1}{4} + r & \frac{1}{4} \end{pmatrix}, \qquad b = \begin{pmatrix} \frac{1}{2} \\ \frac{1}{2} \end{pmatrix}. \tag{3}$$

For one step of length h, the stage states satisfy

$$Z_i = z_n + h\sum_{j=1}^{2} a_{ij} f(t_n + c_j h, Z_j), \qquad i = 1, 2, \tag{4}$$

and the accepted state is

$$z_{n+1} = \Phi_{h,t_n}(z_n) = z_n + h\sum_{i=1}^{2} b_i f(t_n + c_i h, Z_i). \tag{5}$$

The method is implicit: equations (4) determine (Z_1, Z_2) simultaneously.

3 Exact Jacobian of the stage root

Introduce the stage field Jacobians and stage sensitivities

$$F_i := D_z f(t_n + c_i h, Z_i), \qquad S_i := \frac{\partial Z_i}{\partial z_n}. \tag{6}$$

Differentiating (4) with respect to z_n gives

$$S_i = I_{2d} + h \sum_{j=1}^{2} a_{ij} F_j S_j. \tag{7}$$

Equivalently,

$$\underbrace{\begin{pmatrix} I_{2d} - \frac{h}{4} F_1 & -h\left(\frac{1}{4} - r\right) F_2 \\ -h\left(\frac{1}{4} + r\right) F_1 & I_{2d} - \frac{h}{4} F_2 \end{pmatrix}}_{M = D_{(Z_1, Z_2)} R} \begin{pmatrix} S_1 \\ S_2 \end{pmatrix} = \begin{pmatrix} I_{2d} \\ I_{2d} \end{pmatrix}. \tag{8}$$

Here M is the Jacobian of the coupled stage residual. It is also the matrix used by an exact Newton linearization, but it is *not* the Jacobian of the physical one-step map.

Assuming that the converged stage root is regular, the implicit function theorem gives

$$\begin{pmatrix} S_1 \\ S_2 \end{pmatrix} = M^{-1} \begin{pmatrix} I_{2d} \\ I_{2d} \end{pmatrix}. \tag{9}$$

In an implementation, equation (8) should be solved directly; the inverse in (9) is only notation.

4 Exact Jacobian of the physical step

Define the Jacobian of the map (5) by

$$\mathcal{J}_n := D_{z_n} \Phi_{h,t_n}(z_n).$$

Differentiating the accepted update and using (6) yields

$$\boxed{\mathcal{J}_n = I_{2d} + h \sum_{i=1}^{2} b_i F_i S_i = I_{2d} + \frac{h}{2}\left(F_1 S_1 + F_2 S_2\right).} \tag{10}$$

Combining (9) and (10), the same Jacobian can be written as

$$\boxed{\mathcal{J}_n = I_{2d} + h \begin{pmatrix} \frac{1}{2} F_1 & \frac{1}{2} F_2 \end{pmatrix} M^{-1} \begin{pmatrix} I_{2d} \\ I_{2d} \end{pmatrix}.} \tag{11}$$

This is the exact tangent of the ideal converged root. It differentiates the mathematical Gauss–Legendre map, not a finite Newton stopping rule.

5 Direct proof of symplecticity with the step Jacobian

The one-step map is symplectic if and only if

$$\mathcal{J}_n^T \Omega \mathcal{J}_n = \Omega. \tag{12}$$

Set

$$K_i := F_i S_i. \tag{13}$$

Then equations (10) and (7) become

$$\mathcal{J}_n = I_{2d} + h \sum_i b_i K_i, \qquad I_{2d} = S_i - h \sum_j a_{ij} K_j. \tag{14}$$

Expanding the symplecticity defect gives

$$\begin{aligned} \mathcal{J}_n^T \Omega \mathcal{J}_n - \Omega = h \sum_i b_i \left(K_i^T \Omega + \Omega K_i \right) \\ + h^2 \sum_{i,j} b_i b_j K_i^T \Omega K_j. \end{aligned} \tag{15}$$

By the Hamiltonian identity (2),

$$\begin{aligned} K_i^T \Omega S_i + S_i^T \Omega K_i &= S_i^T \left(F_i^T \Omega + \Omega F_i \right) S_i \\ &= 0. \end{aligned} \tag{16}$$

Using the second identity in (14) on both occurrences of I_{2d} therefore gives

$$K_i^T \Omega + \Omega K_i = -h \sum_j a_{ij} \left(K_i^T \Omega K_j + K_j^T \Omega K_i \right). \tag{17}$$

Substitute (17) into (15). Renaming i and j in the second term arising from (17) produces

$$\boxed{\mathcal{J}_n^T \Omega \mathcal{J}_n - \Omega = h^2 \sum_{i,j} \left(b_i b_j - b_i a_{ij} - b_j a_{ji} \right) K_i^T \Omega K_j.} \tag{18}$$

Consequently, the defect vanishes whenever the Runge–Kutta coefficients obey

$$\boxed{b_i a_{ij} + b_j a_{ji} = b_i b_j, \qquad i, j = 1, 2.} \tag{19}$$

6 Verification for the Gauss–Legendre coefficients

For the diagonal terms in (19),

$$2b_1a_{11} - b_1^2 = 2\left(\frac{1}{2}\right)\left(\frac{1}{4}\right) - \frac{1}{4} = 0, \qquad 2b_2a_{22} - b_2^2 = 0. \tag{20}$$

For the off-diagonal terms,

$$\begin{aligned} b_1a_{12} + b_2a_{21} - b_1b_2 &= \frac{1}{2}\left(\frac{1}{4} - r\right) + \frac{1}{2}\left(\frac{1}{4} + r\right) - \frac{1}{4} \\ &= 0. \end{aligned} \tag{21}$$

The case $(i, j) = (2, 1)$ is the same equality with the two summands exchanged. Thus every coefficient multiplying $K_i^T \Omega K_j$ in (18) is zero, and hence

$$\boxed{\mathcal{J}_n^T \Omega \mathcal{J}_n = \Omega.} \tag{22}$$

Therefore the two-stage Gauss–Legendre method is symplectic when its implicit stage equations are solved exactly.

7 Symmetry and time reversibility

Symmetry is a property distinct from symplecticity. The method is symmetric when its backward step is exactly the inverse of its forward step. For the possibly time-dependent problem (1), this means

$$\boxed{\Phi_{-h,t_n+h} \circ \Phi_{h,t_n} = \mathrm{Id}\,.} \tag{23}$$

For an autonomous problem, equation (23) reduces to $\Phi_{-h} = \Phi_h^{-1}$.

For the forward step, write

$$f_1 = f(t_n + c_1 h, Z_1), \qquad f_2 = f(t_n + c_2 h, Z_2). \tag{24}$$

Equations (4) and (5) are then

$$\begin{aligned} Z_1 &= z_n + h(a_{11} f_1 + a_{12} f_2), \\ Z_2 &= z_n + h(a_{21} f_1 + a_{22} f_2), \qquad (25) \\ z_{n+1} &= z_n + h(b_1 f_1 + b_2 f_2). \qquad (26) \end{aligned}$$

Now start from z_{n+1} at time $t_n + h$ and apply the same method with step $-h$. Its stages $\widehat{Z}_1, \widehat{Z}_2$ satisfy

$$\widehat{Z}_i = z_{n+1} - h \sum_{j=1}^{2} a_{ij} f(t_n + h - c_j h, \widehat{Z}_j). \tag{27}$$

The Gauss nodes are reflected about the midpoint:

$$1 - c_1 = c_2, \qquad 1 - c_2 = c_1. \tag{28}$$

Thus the backward stage times are the forward stage times in reverse order. We shall verify that the backward stages are

$$\boxed{\widehat{Z}_1 = Z_2, \qquad \widehat{Z}_2 = Z_1.} \tag{29}$$

Under the identification (29), the first backward stage equation becomes

$$\begin{aligned} \widehat{Z}_1 &= z_{n+1} - h(a_{11} f_2 + a_{12} f_1) \\ &= z_n + h\left[(b_1 - a_{12}) f_1 + (b_2 - a_{11}) f_2\right]. \end{aligned} \tag{30}$$

For the coefficients (3),

$$b_1 - a_{12} = a_{21}, \qquad b_2 - a_{11} = a_{22}. \tag{31}$$

Consequently,

$$\widehat{Z}_1 = z_n + h(a_{21} f_1 + a_{22} f_2) = Z_2.$$

Likewise, the second backward stage satisfies

$$\begin{aligned} \widehat{Z}_2 &= z_{n+1} - h(a_{21} f_2 + a_{22} f_1) \\ &= z_n + h\left[(b_1 - a_{22}) f_1 + (b_2 - a_{21}) f_2\right]. \end{aligned} \tag{32}$$

Since

$$b_1 - a_{22} = a_{11}, \qquad b_2 - a_{21} = a_{12}, \tag{33}$$

we obtain

$$\widehat{Z}_2 = z_n + h(a_{11} f_1 + a_{12} f_2) = Z_1.$$

The proposed reversed stages therefore solve the coupled backward stage equations exactly.

The output of the backward step is now

$$\begin{aligned}\widehat{z}_n &= z_{n+1} - h(b_1 f_2 + b_2 f_1)\\ &= z_n + h(b_1 f_1 + b_2 f_2) - h(b_1 f_2 + b_2 f_1)\\ &= z_n,\end{aligned} \tag{34}$$

where the last equality uses $b_1 = b_2 = 1/2$. This proves (23).

More generally, an s-stage Runge–Kutta method is symmetric when its coefficients are invariant under stage reversal:

$$\boxed{c_i = 1 - c_{s+1-i}, \qquad b_i = b_{s+1-i}, \qquad a_{ij} = b_{s+1-j} - a_{s+1-i,s+1-j}.} \tag{35}$$

The coefficients in (3) satisfy all three identities for $s = 2$.

Differentiating the map identity (23) also gives the Jacobian form of reversibility:

$$\boxed{D\Phi_{-h,t_n+h}(z_{n+1})\, D\Phi_{h,t_n}(z_n) = I_{2d}.} \tag{36}$$

Thus the backward-step Jacobian is exactly the inverse of the forward-step Jacobian. As with symplecticity, a finite Newton tolerance and floating-point round-off can produce a small measured reversibility defect even though the ideal implicit method is exactly symmetric.

8 Consequences and numerical interpretation

For one guiding-centre particle, $\mathcal{J}_n \in \mathbb{R}^{2\times 2}$ and

$$\mathcal{J}_n^T \Omega \mathcal{J}_n = \det(\mathcal{J}_n)\Omega.$$

Equation (22) therefore implies

$$\det(\mathcal{J}_n) = 1,$$

so the one-step map preserves oriented area. In dimensions greater than two, unit determinant is only a consequence of symplecticity, not an equivalent test.

If $\mathcal{J}_n$ denotes the local Jacobian at step n, the accumulated flow tangent after N steps is

$$\mathcal{P}_N = \mathcal{J}_{N-1} \cdots \mathcal{J}_1 \mathcal{J}_0.$$

Since a product of symplectic matrices is symplectic,

$$\mathcal{P}_N^T \Omega \mathcal{P}_N = \Omega.$$

The algebraic result concerns the exact root and the exact tangent (10). In floating-point computations, a finite Newton tolerance, round-off, or a finite-difference approximation of the map Jacobian produces a small nonzero measured defect

$$\left\| \mathcal{J}_n^T \Omega \mathcal{J}_n - \Omega \right\|.$$

That numerical floor does not contradict the exact symplecticity proved above.
